Figure 1a. Relative survival of patients with breast cancer (men) by period of diagnosis. Included in the evaluation are 484 cases diagnosed between 1988 and 2019.

The survival results of the SEER program (Surveillance, Epidemiology, and End Results) of the American National Cancer Institute (NCI) are summarized as the period of diagnosis from 2000 to 2016, and are represented by colored diamonds in order to facilitate comparisons between MCR and SEER.

The presented survival curves are derived from clinical records with valid follow-up informations, which means that death certificate cases (DCO) cases are omitted from the analysis. With this one restriction, the MCR has provided population-based statistics since 1998, collecting data on all cancer cases in the region of southern Bavaria. Historical data of previous time periods can be heavily selected, therefore, univariate survival comparisons of the presented time periods must be carefully considered. Nonetheless, all calculable survival curves are depicted to facilitate the comparison of long time follow-up analyses of relative survival between particular cancers.

Figure 4a. Relative survival of patients with breast cancer (men) by TNM staging. For 467 of 484 cases diagnosed between 1988 and 2019 valid data could be obtained for this item. For a total of 459 cases an evaluable classification was established. The accumulated percentage exceeds the 100 % value because patients are potentially considered in more than one subgroup. The grey line represents the subgroup of 25 patients with missing values regarding TNM staging (5.2 % of 484 patients, the percent values of all other categories are related to n=459).

Figure 5a. Time to first progression of 429 patients with breast cancer (men) diagnosed between 1998 and 2019 (in solid cancers M0 only) estimated by cumulative incidence function (CI, solid line) accounting for death as competing risk and by inverse Kaplan-Meier estimate (1-KM, dashed line). The frequency of events may be underestimated due to underreporting.

Table 5b. Time to first progression of patients with breast cancer (men) for period 1998-2019 (N=429), also showing the total of progression events (Events) and of deaths as competing risk (compet.).

Figure 5c. Observed post-progression survival of 110 patients with breast cancer (men) diagnosed between 1998 and 2019. These 110 patients with documented progression events during their course of disease represent 25.6 % of the totally 429 evaluated cases (incl. M1, n=36, 8.4 %). Patients with cancer relapse documented via death certificates only were excluded (n=21, 4.9 %). Multiple progression types on different sites are included in the evaluation even when not occurring synchronously.

Medical record documentation often lacks the linguistic severity to distinguish between local relapse, regional lymph node metastasis and distant spread in solid cancers. Frequently, the statement “not specified” is the only information in registries regarding relapse of the disease. The category “Any type” denotes all cases who suffered from at least one relapse during the course of disease (incl. primary M1-status). Although, the real number of relapsed patients is likely to be much higher. The accumulated percentage of patients with local relapse or distant metastasis exceeds the 100 % value because patients are potentially considered in more than one subgroup.
