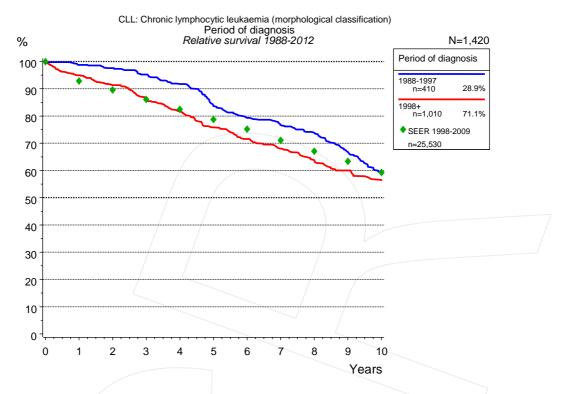

Figure 1a. Relative survival of patients with chronic lymph. leukaemia (morph.) by period of diagnosis. Included in the evaluation are 1,420 cases diagnosed between 1988 and 2012.

The presented survival curves are derived from clinical records with valid follow-up informations, which means that death certificate cases (DCO) cases are omitted from the analysis. With this one restriction, the MCR has provided populationbased statistics since 1988, collecting data on all cancer cases in the region of southern Bavaria. Historical data of previous time periods can be heavily selected, therefore, univariate survival comparisons of the presented time periods must be carefully considered. Nonetheless, all calculable survival curves are depicted to facilitate the comparison of long time follow-up analyses of relative survival between particular cancers.

Table 2d. Conditional relative 2 / 5-year survival of patients with chronic lymph. leukaemia (morph.) by gender for period 1988-2012 (N=1,420).

Conditional relative survival rates refer to the relative survival probability, in this case for 2 and 5 years after cancer diagnosis, compared to the age- and sex-matched population (=100%) under the condition of being alive for a certain time period (x-axis in Figure 2a). The results illustrate to what extent the cancer induced mortality of particular subgroups declines in the subsequent years after detection of the malignancy. For instance, according to the presented survival statistics, patients in the subgroup gender="Male", who are alive at least 3 years after cancer diagnosis, the conditional relative 2-year survival rate is 88.1% (n=596).

Table 3b. Observed (obs.) and relative (rel.) survival of patients with chronic lymph. leukaemia (morph.) by age category for period 1988-2012 (N=1,420).

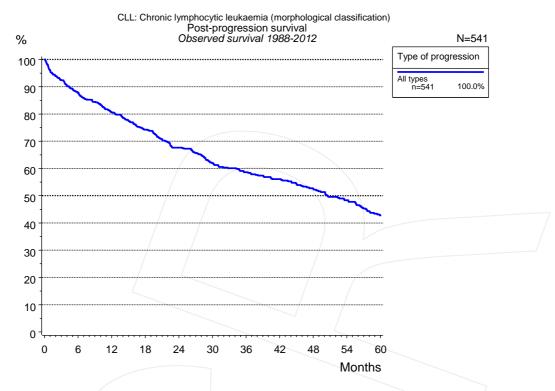

Figure 5a. Observed post-progression survival of 541 patients with chronic lymph. leukaemia (morph.) diagnosed between 1988 and 2012 (incl. M1). These 541 patients with documented progression events during their course of disease represent 38.1% of the totally 1,420 evaluated cases. Patients with cancer relapse documented via death certificates only were excluded (n=105, 7.4%).

Medical record documentation often lacks the linguistic severity to distinguish between local relapse, regional lymph node metastasis and distant spread in solid cancers. Frequently, the statement "not specified" is the only information in registries regarding relapse of the disease. The category "All types" denotes all cases who suffered from at least one relapse during the course of disease (incl. primary M1-status). Although, the real number of relapsed patients is likely to be much higher. The accumulated percentage of patients with local relapse or distant metastasis exceeds the 100% value because patients are potientially considered in more than one subgroup.
